## Stochastic Finance (2016–17 M3) Final Exam, April 20, 2017

BM stands for Brownian motion. RN and RV stand for random number and random variable respectively.

- 1. [4 points] Stochastic calculus Find all surviving terms in stochastic calculus
  - (a)  $dB_t \cdot dt$
  - (b)  $(dB_t)^2$
  - (c)  $dx \cdot dt$
  - (d)  $dB_t^1 \cdot dB_t^2$  for the two independent BMs,  $B_t^1$  and  $B_t^2$
- 2. [6 points] Option pricing under the BSM and normal model Assume that a stock's daily price change is 1.5% of the current price. What is the annual volatility of the stock under the Black-Scholes-Merton model and the normal model? What is the price of the at-the-money call option maturing in 3 months under the two models? Assume that  $S_0 = 100$ , r = q = 0 and there are 256 trading days in one year. You may use the following CDF values for the standard normal distribution N(z).

z	0.02	0.04	0.06	0.08	0.10	0.12	0.14	0.16
N(z)	0.508	0.516	0.524	0.532	0.540	0.548	0.556	0.564

3. [5 points] Option delta under the BSM model By directly computing the derivative, show that the delta of a call option (i.e., sensitivity with respect to the underlying stock price  $S_0$ ) is

$$D = \frac{\partial C_0}{\partial S_0} = N(d_1) \quad \text{with} \quad d_1 = \frac{\log(S_0 e^{rT}/K)}{\sigma\sqrt{T}} + \frac{1}{2}\sigma\sqrt{T}.$$

Since the terms  $d_1$  and  $d_2$  are defined through  $S_0$ , you should also differentiate  $d_1$  and  $d_2$  rather than treating them as constants.

4. [9 points] Volatility of a stock denominated in difference currency If you invest in a stock listed in a foreign country, you are exposed to the risk of both the stock price (in the foreign currency) and the foreign exchange rate. We are going to see volatility of the value of the stock in the domestic currency. Assume that you invested in Amazon's stock (NASDAQ ticker AMZN, which is currently about 900 USD) and the volatility is 20%. Also assume that the volatility of the foreign exchange rate (currency code USDCNY, X CNY = 1 USD, which is 6.89 recently) and the volatility is 5%. Also assume that the correlation between the stock price change and the FX rate change is given as  $\rho$  (not necessarily independent!). The SDEs for the processes can be written as

Stock price: 
$$\frac{dS_t}{S_t} = r_S dt + \sigma_S dB_t^S \quad \text{where} \quad \sigma_S = 20\%$$
 FX rate: 
$$\frac{dF_t}{F_t} = r_F dt + \sigma_F dB_t^F \quad \text{where} \quad \sigma_F = 8\%$$
 Correlation: 
$$dB_t^S \cdot dB_t^F = \rho \, dt.$$

- (a) Derive the SDE for the stock value in CNY. That is, calculate  $d(F_t S_t)$ .
- (b) Re-write the SDE with single BM, let's say  $B_t^{FS}$ , and find the volatility of the stock price in CNY. This is the extension of our mid-term exam problem. You need to find c such that

$$c dB_t^{FS} = a dB_t^S + b dB_t^F$$
 with  $dB_t^S \cdot dB_t^F = \rho dt$ 

- (c) What is the minimum/maximum value of the combined volatility? Under which scenario?
- 5. [6 points] Solving SDE Solve the modified Cox-Ingersoll-Ross (CIR) model.

$$dX_t = \frac{\sigma^2}{4}dt + \sigma\sqrt{X_t}\,dB_t.$$

The original CIR model has the drift term  $a(b-X_t)dt$  instead of  $(\sigma^2/4)dt$  and was originally proposed for the movements of interest rates.
